**Abstract** – The Thai freshwater fungi are reviewed. Substrates range from baits (*Dipterocarpus alatus*, *Licuala longicalycata* and *Xylia dolabriformis*) to submerged natural wood, collected in northern (Chiang Mai and Chiang Rai), and southern (Narathiwat) and northeastern (Nakorn Ratchasima) parts of the kingdom. The checklist comprises 173 identified species (including 34 Ingoldian fungi) published up to the end of 2010 and is supported with references. The taxa belong to 112 genera, including 30 *Sordariomycetes*, 12 *Dothideomycetes* and 70 anamorphic genera. The most frequently collected genera are the hyphomycetes *Biflagellospora*, *Canalispodium*, *Dactylaria*, *Dictyosporium* and *Xylomyces*. Five new genera and 26 new species were first described from Thai freshwater habitats. Fungal diversity in different substrates and Sørensen's index in different sites are discussed.

### Substrate / new species / Sørensen's index / lignicolous freshwater fungi

## INTRODUCTION

Freshwater fungi are a complicated group because of their broad definition — “fungi that for the whole or part of their life cycle rely on freshwater” (Thomas, 1996). Lignicolous freshwater fungi comprise freshwater ascomycetes (Cai *et al.*, 2003b) and anamorphic fungi known as hyphomycetes and coelomycetes (Goh & Tsui, 2003) while Ingoldian fungi are usually found in river foam and occur on decaying submerged leaves. For methods to study freshwater fungi refer to Tsui *et al.* (2003).

Until the end of the last century, freshwater fungi have been reported from locations where mycologists were based or had visited and mainly including Australia (Hyde, 1992a, 1992b, 1993a, 1993b, 1995a, 1995b, 1995c, 1996; Hyde & Goh, 1998, 1999b; Hyde & Seifert, 1992; Hyde & Wong, 1999; Hyde *et al.*, 1996a, 1996b, 1997) and the USA (Shearer, 1989; Shearer & Crane, 1986) and UK (Hyde & Goh, 1999a; Kane *et al.*, 2002). Researchers have more recently focused on the other areas, such as Brunei (Fryar *et al.*, 2004; Ho *et al.*, 2001; Hyde *et al.*, 2002), China (Cai *et al.*, 2002, 2005; Luo *et al.*, 2004), Hong Kong (Tsui & Hyde,

2004; Tsui *et al.*, 2000, 2001, 2002) and Malaysia (Ho *et al.*, 2001). There have also been several papers on lignicolous freshwater fungi from Thailand (e.g. Jones *et al.*, 1999; Marvanová & Hywel-Jones, 2000; Sivichai & Boonyuen, 2010; Sivichai & Hywel-Jones, 1999; Sivichai *et al.*, 1998, 2000a; Sri-indrasutdhi *et al.*, 2010).

Tubaki was the first mycologist to survey the freshwater fungi in Thailand. He found 40 Ingoldian fungi from foam-samples (Tubaki *et al.*, 1983). Eighty species and 73 species were reported from the baited timbers (*Dipterocarpus alatus* and *Xylia dolabriformis*) respectively from two sites of northeastern Thailand (Sivichai *et al.*, 2000b, 2002). Sivichai & Boonyene (2004) reviewed freshwater higher fungi in Thailand and listed 158 identified genera. Subsequent studies on natural submerged wood were carried out in northern Thailand (Hu *et al.*, 2010; Kurniawati *et al.*, 2010). There is no publication that brings together all of these records. In this paper information on Thai freshwater fungi is therefore collated and reviewed. A checklist of identified Thai freshwater fungi published until 2010 is provided.

## RESULTS

### The collection plots

Most records of freshwater fungi were from the north (Chiang Mai and Chiang Rai), south (Narathiwat) and northeast (Nakorn Ratchassima) of Thailand (Fig. 1). Ingoldian fungi were surveyed from Kanchanaburi and Songkhla. Besides these provinces, collections of *Canalisporium* spp. have been made in Lop Buri, Petchaburi, Nakhon Nayok, Chanthaburi, Prachuap Khiri Khan and Krabi provinces (Sri-indrasutdhi *et al.*, 2010), while *Berkleasmium typhae* Somrith. & E.B.G. Jones was collected in Pathum Thani (Somrithipol & Jones, 2003). Collection sites include mountain parks (Hu *et al.*, 2010; Kurniawati *et al.*, 2010) and peat swamp forests (Pinnoi *et al.*, 2006; Pinruan *et al.*, 2002, 2007). Habitats include lentic (e.g. lake: Hu *et al.*, 2010) and lotic sites (e.g. streams: Hu *et al.*, 2010; Kurniawati *et al.*, 2010; Sivichai *et al.*, 2000b) (Table 3).

### Diversity of freshwater fungi in Thailand

Fig. 1. The collection plots (<http://www.maps-gps-info.com/mp-th.html>).

A list of 173 Thai freshwater fungi which have been identified to species level until 2010 is provided alphabetically in Table 1. They belong to 112 genera, including species in 30 genera (25.9%) belonging to the *Sordariomycetes*, species in 12 genera (10.7%) belonging to the *Dothideomycetes* and 70 anamorphic genera (63.4%). The largest family is Annulatasaceae with 6 genera and 9 species (taxonomy based on Lumbsch & Huhndorf, 2010). The most frequent hyphomycetes are *Canalisporium* (7 species), *Dactylaria* (5 species), *Biflagellospora* (4 species) *Dictyosporium* (4 species) and *Xylomyces* (4 species).

Eighty-eight species have been reported from Nakorn Ratchassima, 57 species from Chiang Mai, 51 species from Narathiwat, 25 species from

Chiang Rai, 22 species from Songkhla and 15 species from Kanchanaburi provinces. This may indicate that the fungal diversity in northeast Thailand is more abundant than other parts, but is more likely to represent intensity of studies. Interestingly, some common freshwater species such as *Canalisporium caribense* (Hol.-Jech. & Mercado) Nawawi & Kuthub. can be found at nearly every site investigated, no matter test blocks or naturally submerged wood, except for being absent in one artificial lake in Chiang Mai. *Acrogenospora sphaerocephala* (Berk. & Broome) M.B. Ellis, *Annulatascus velatispora* K.D. Hyde, *Aquaphila albicans* Goh, K.D. Hyde & W.H. Ho, *Canalisporium pulchrum* (Hol.-Jech. & Mercado) Nawawi & Kuthub., *Candelabrum brocchiatum* Tubaki, *Helicomyces roseus* Link and *Phaeoisaria clematidis* (Fuckel) S. Hughes were found at least at three different sites.

Another 87 taxa were only reported to generic level and are not included in Table 1 but are listed in Table 2. The species identities of these collections await future study. Totally, 199 genera were reported from Thailand until 2010 and 36 genera are new reports since 2004 (Sivichai & Boonyene, 2004).

### Comparison of freshwater fungi in different substrates

Substrates can be divided into three types: naturally submerged wood (Hu *et al.*, 2010; Kurniawati *et al.*, 2010; Sivichai *et al.*, 2002), naturally submerged palm material such as *Licuala longicalycata* (Pinruan *et al.*, 2007) and baited test blocks of wood and palms such as *Xylia dolabriformis* and *Dipterocarpus alatus* (Sivichai *et al.*, 2000b, 2002) (Table 3). Ninety-two species have been reported from submerged palm material and 81 species from naturally submerged wood. Twenty-four species (26% of the total for palm and 29% of the total for wood)

Table 3. Bio-diversity index of four diversity studies (*D* = *Dipterocarpus alatus*, *X* = *Xylia dolabroformis*, S = stream, L = lake, R = river)

were shared between submerged wood and palm material. The low percentage of overlap shows that fungal diversity is different on submerged palm material and wood. Sivichai (2002) thought key factors include surface available area for colonisation, the presence of bark or treatment of the baits by autoclaving before exposure. That different substrates support different fungal diversity has also been reported by Cai *et al.* (2003a). They studied freshwater fungi in the Philippines and found submerged bamboo supports a different and diverse group of fungi in comparison to submerged wood.

As opposed to naturally occurring wood, the average number of fungal taxa occurring per sample on submerged baits is higher (5.6-7.1 vs. 0.69-4.5) (Table 3). Ho (1998) reported that the average number of fungal species occurring on baits of *Machilus velutina* and *Pinus massoniana* were 4.3 and 3.8, which is higher than on natural wood (2.9, 2.9 and 0.7). Cai *et al.* (2003a) found that freshwater fungi on natural wood and bamboo in the Liput River in the Philippines had a relatively high average of 2.28 species per sample, while Luo *et al.* (2004) reported 1.68 per sample from Lake Dianchi, China. These figures are generally lower than on baits.

### **Comparison of Sørensen's index in different sites**

Biodiversity index of four diversity papers are compared in Table 3. Hu *et al.* (2010) studied a lake and a stream in Chiang Mai and showed that lotic habitats have a higher fungal diversity than lentic habitats. The reason is probably low oxygen availability and perhaps affects of damming and lower substrate variety. Sørensen's indexes from four studies on freshwater diversity are listed in Table 4. Ignoring the sites appearing in the same paper, the highest Sørensen's index is between Khao Yai stream and Tad Ta Phu Stream (0.245). That is because both of the sites are in Khao Yai National Park. It also shows high similarity between three collections in Mae Chan and MRC stream (all are more than 0.1). This coincides with our intuition because both of the sites are in northern Thailand. The lowest Sørensen's index is 0.053, which is between a stream in Mae Chan and Tad Ta Phu Stream. The Sørensen's index between MRC Lake and other sites is no more than 0.09, while between MRC stream and other sites is no less than 0.09.

### **New freshwater fungi from Thailand**

Studies on the freshwater fungi in the Thailand have yielded five new genera and 26 new species, of which 15 are from submerged palm material and eleven are from submerged wood and leaves (Table 1).

### **CONCLUSION**

Our information concerning Thai freshwater fungi is far from complete. Future collections are needed, particularly in less studied regions. Even water bodies in Chiang Rai should be studied further as only 25 species have so far been reported. As more sites are studied, more taxa will be reported. New taxa will also

Table 4. Comparison of Sørensen's index of four diversity studies (Sørensen's index of similarity ( $S'$ ) =  $2c / (a+b)$ ; a = total number of species from site 1; b = total number of species from site 2; c = number of common species to both sites)

inevitably be found. There are two reasons for this: a) 217 species have been reported from Hong Kong (<http://fungi.life.illinois.edu/>). Both Thailand and Hong Kong belong to tropical/subtropical areas and Thailand is very much larger than Hong Kong with a much higher plant diversity; b) there are 87 taxa reported to generic level only and once these are studied further it is likely that many will be found to be new species.

Cai *et al.* (2003) compared freshwater fungi on submerged bamboo and wood and found a different and diverse group of fungi in comparison to wood and bamboo. The same conclusion is likely to be found in Thailand but this has not been studied.

In summary, we hope that the information presented herein will prompt future studies to document freshwater fungi of Thailand.

**Acknowledgement.** Thanks for the State Scholarship Fund of the Ministry of Education of the P. R. China (No. 2010853029). The Global Research Network for Fungal Biology (GRNFB) and King Saud University are also thanked for supporting this research.
